

73275

DRAFT

Micropoikilitic Impact melt Breccia  
429.6 grams

Figure 1: Photo of 73275. NASA S73-16925. Cube is 1cm. Note zap pits.

## Introduction

Lunar sample 73275 was collected from station 3, Apollo 17 (Wolfe et al. 1981). It was found sitting perched on the regolith near the rim of a small crater (Ballet Crater?). It is rounded and covered with micrometeorite craters on all sides except where a piece broke off (figure 1).

73275 is an impact melt breccia with fine-grained poikilitic matrix and minor vesicularity (figure 2). It has a crystallization age of about 3.9 b.y. with exposure to cosmic rays about 140 m.y.

## Petrography

Ryder (1993) describes 73275 as a clast-bearing micropoikilitic impact melt breccia with a composition similar to other samples thought to be from the Serenitatis impact event.

Simonds et al. (1974) describes the matrix of 73275 as subophitic-micropoikilitic, giving the grain size of

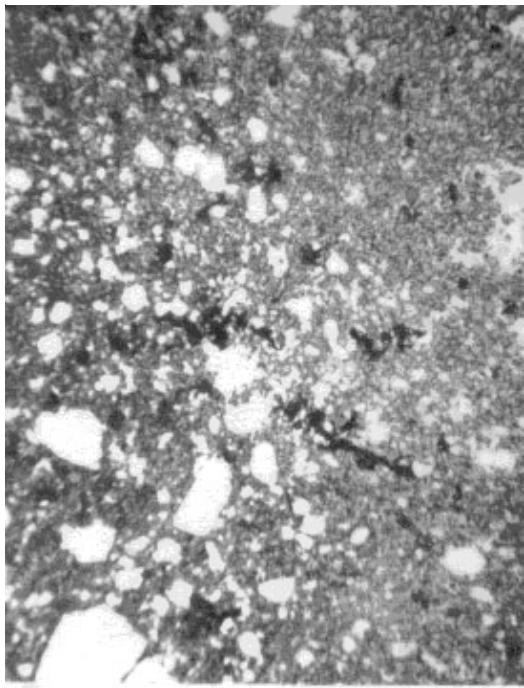

plagioclase as 10-50 microns (figure 2). Heuer et al. (1974) and Radcliffe et al. (1974) describe 73275 as a recrystallized breccia with large clasts of plagioclase (0.3-1.0 mm), orthopyroxene (0.1-0.2 mm) and smaller olivine (0.05-0.2 mm). They reported the calcic cores of plagioclase ( $An_{90-97}$ ) have sodic overgrowths ( $An_{85-90}$ ) and the pyroxene has wide exsolution lamellae indicating prolonged annealing at high temperature.

73275 apparently lacks “flow banding” and relic aphanitic clasts that are characteristic of adjacent samples (732xx).

## Mineralogy

**Pyroxene:** Simonds et al. (1974) determined the pyroxene compositions in the matrix and small clasts (figure 3).

**Plagioclase:** Heuer et al. (1974) reported plagioclase composition ( $An_{90-97}$ ).

*Figure 2: Photomicrograph of thin section of 73275 showing “micropoikilitic” texture (from Ryder 1993). Field of view is 2 mm.*

**Metallic iron:** Goldstein et al. (1976) analyzed the Ni, Co and C content of iron grains found interstitial to silicates in 73275 (Ni = ~6%, Co = ~0.6%).

**Cohenite:** Goldstein et al. (1976) found cohenite ((Fe,Ni)<sub>3</sub>C) apparently exsolved from kamacite (figure 4 and 5). The carbon (and Ni) is probably of meteoritic origin.

## Chemistry

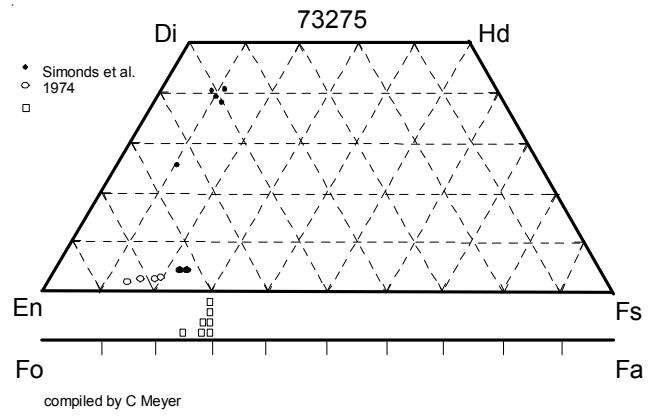

The chemical composition of 73275 is generally similar to that of the other three breccias and to that of 77135 from a boulder on the other side of the Taurus-Littrow valley (figure 6). Morgan et al. (1976) found the meteoritic siderophile elements were a match with other samples from the Serenitatis Basin (table 1).

## Radiogenic age dating

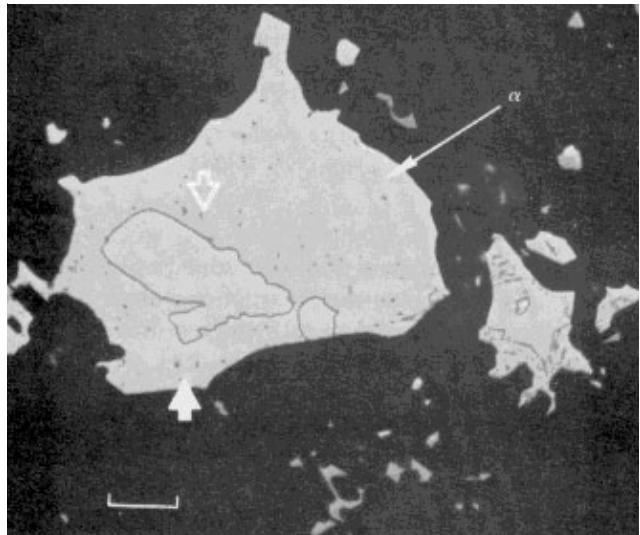

Turner and Cadogen (1975) dated 73215 at  $3.96 \pm 0.05$  b.y. by the Ar 39/40 method (figure 7). Nyquist et al. (1974) and Oberli et al. (1978) determined whole rock Rb-Sr, Sm-Nd and U-Th-Pb isotopic data.

## Cosmogenic isotopes and exposure ages

Turner and Cadogen (1975) determined the cosmic ray exposure age as 160 m.y. by <sup>38</sup>Ar (figure 7). Crozaz et

*Figure 4: Reflected light photo of metallic iron grain in 73275,68 showing cohenite included in kamacite (Goldstein et al. 1976). Scale bar is 16 microns.*

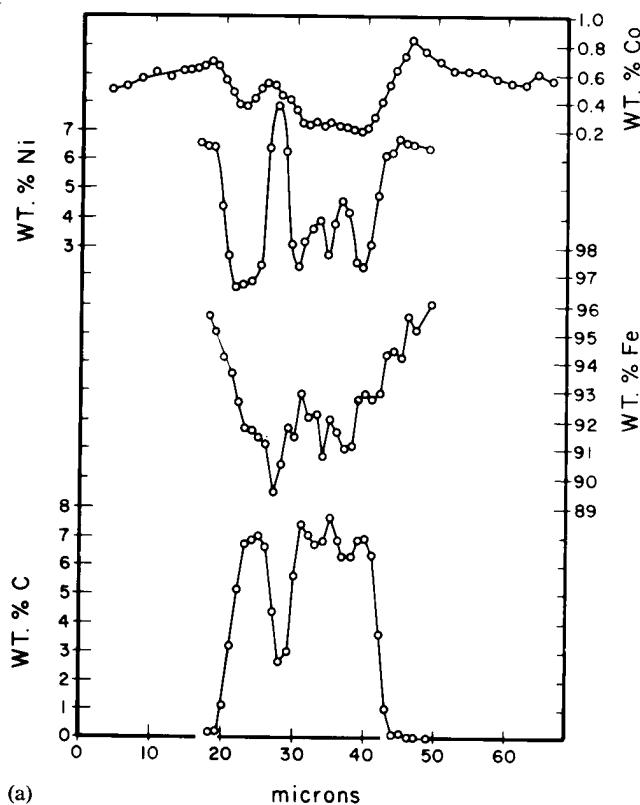

al. (1974) determined the CRE age as 139 m.y. by <sup>81</sup>Kr. Crozaz et al. (1974) and Goswami and Lal (1974) determined cosmic ray track density yielding “ages” in the range of a few m.y.

## Other Studies

Nagata et al. (1974) and Housley et al. (1976) studied the magnetic properties of 73275. Huffman et al. (1974) and Huffman and Dunphyre (1975) studied 73275 by Mossbauer spectroscopy.

## Processing

A slab was cut from 73275 (figure 8). There are 16 thin sections of 73275.

### Summary of Age Data for 73275

	Ar/Ar	U/Pb
Turner and Cadogen 1975	$3.96 \pm 0.05$ b.y.	
Oberli et al. 1978		$\sim 4.42$ b.y.

**Caution:** Data is with old decay constants.

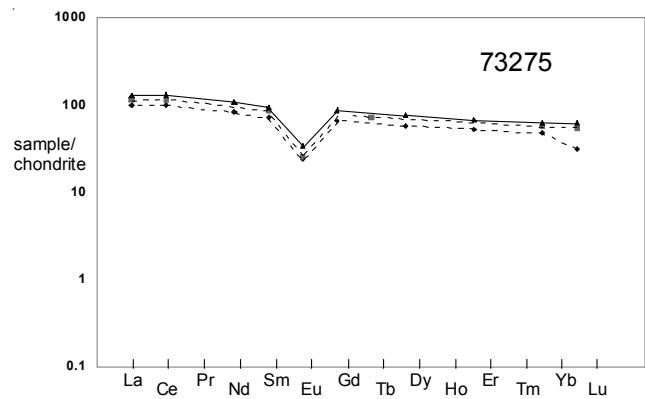

Figure 6: Normalized rare-earth-element diagram for 73275 (solid) compared with that of 73215 and 73235 (dashed). Data from Wiesmann and Hubbard 1975.

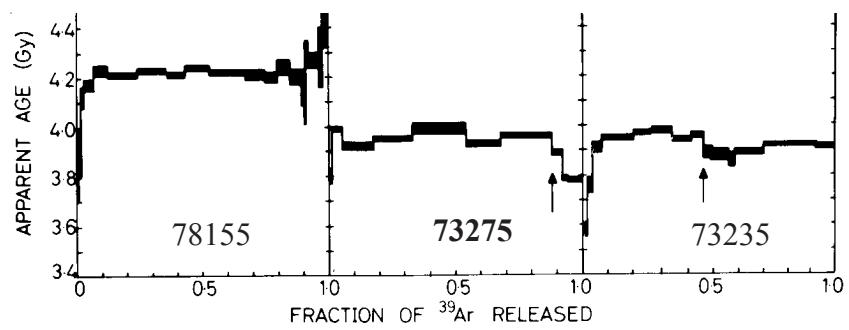

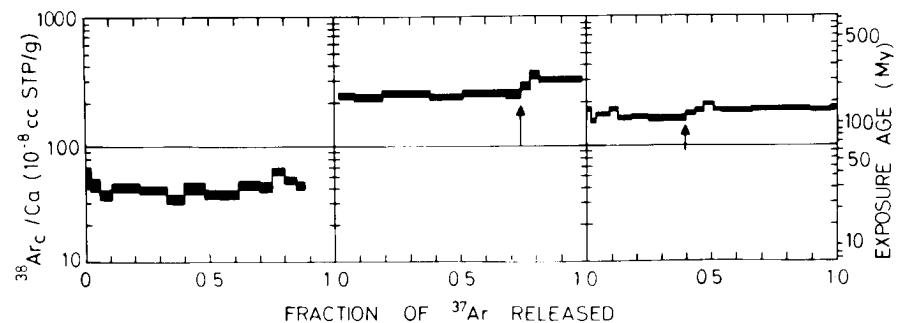

Figure 7: Ar release pattern for 73235, 73275 and 78155 (from Turner and Cadogen 1975).
